There is much variation in the conventional approach to spinal stabilization, including in the length of a fusion device that is inserted in a patient's spine. In some approaches, relatively long insertion devices may be used, to help insure that the chosen fusion device is able to contact the endplates and/or other vertebral surfaces for stability. However, such a long insertion device is often difficult to insert into a patient, and is also more likely to inadvertently cause trauma to tissue surrounding the patient's spine. In some spinal stabilization approaches, relatively short insertion devices are used to help reduce the invasiveness of the procedure and to reduce the risk of damaging surrounding tissue. In one such approach, a stabilization member may be inserted in a cavity formed in an elongated bore provided in the adjacent vertebrae. The bore may have a length that is between a fraction of an inch and several inches, and may allow the stabilization member to contact the endplates and/or other vertebral surfaces. However, such relatively short insertion devices may not have sufficient length to provide a desired alignment or other stability in certain 82157476af
